### 3.2 Matrix Algebra

**Definition:** The  $i$ th standard basis vector, denoted  $e_i$ , for  $\mathbb{R}^n$  is the length  $n$  vector consisting of all zeros except a one in the  $i$ th position. The set of all standard basis vectors for  $\mathbb{R}^n$  is called the standard basis. When it matters, we will regard  $e_i$  a column vector.

**Theorem** Let  $A = [a_1 \dots a_n]^t$  be an  $n \times k$  matrix and  $B$  be a  $k \times m$  matrix. Then the rows of  $AB$  are  $a_1B, \dots, a_nB$ .

**Example** Let's consider the square matrices  $A = [2, -1; 1, 3]$  and  $B = [4, -2; -1, 1]$ . We can think of  $AB$  in two ways. Either  $A$  is acting on  $B$  by combining the rows or  $B$  is acting on  $A$  by combining the columns.

We should think about what the standard basis does. So what is  $e_i^t B$ ?

We should think of  $[2, -1]$  as  $2e_1^t - e_2^t$ .

### 3.3 Inverses

The composition of  $f$  and  $g$  is the function  $(f \circ g)$  where  $(f \circ g)(x) = f(g(x))$ .

**Definition:** Let  $A, B$  be sets and  $f : A \rightarrow B$  be a function. Then the (two-sided) inverse of  $f$  is a function  $g : B \rightarrow A$  such that  $g \circ f$  is the identity on  $B$  (which means  $(g \circ f)(x) = x$ ) and  $f \circ g$  is the identity on  $A$ . We often denote  $g$  here by  $f^{-1}$ .

The goal is to invert linear transforms. Let  $T : \mathbb{R}^m \rightarrow \mathbb{R}^n$  be linear transform. When can  $T$  be invert? It has to be one-to-one at least. Suppose  $T(x_1) = T(x_2)$ . Then by applying  $T^{-1}$ , we have  $x_1 = x_2$ . This implies  $n \geq m$ . By using the same argument,  $T^{-1} : \mathbb{R}^n \rightarrow \mathbb{R}^m$  must be one-to-one as well so  $m \geq n$ . Therefore,  $n = m$ .

**Theorem:** Suppose  $T : \mathbb{R}^m \rightarrow \mathbb{R}^n$  is a linear transform such that  $T(x) = Ax$ . Then  $T$  is invertible if and only if  $m = n$  and the columns of  $A$  are linearly independent (or spanning).

Let's  $T : \mathbb{R}^2 \rightarrow \mathbb{R}^2$  be the linear transform given by  $T(x) = [1, 2; 3, 4]x$ . So we know  $T(1, 0) = (1, 2)$  and  $T(0, 1) = (3, 4)$ . This implies  $T^{-1}(1, 2) = (1, 0)$  and

$T^{-1}(3, 4) = (0, 1)$ . To determine  $T^{-1}$ , we just need to know what  $T^{-1}(1, 0)$  and  $T^{-1}(0, 1)$  are. Row reduction!

The determinant of a 2,2 matrix is blah. Here's the formula for the inverse of a 2,2 matrix.

**Theorem:** Let  $A$  and  $B$  be invertible matrices and  $C$  and  $D$  be matrices. Then

- $A^{-1}$  is also invertible.
- $AB$  is invertible. The inverse is given by  $(AB)^{-1} = B^{-1}A^{-1}$ .
- If  $AC = AD$  then  $C = D$
- If  $CA = DA$  then  $C = D$

**Theorem:** Let  $A$  be a  $n \times n$  matrix. Let  $S$  be the columns of  $A$ . Let  $T(x) = Ax$ . Then the following are equivalent:

- $S$  spans  $\mathbb{R}^n$
- $S$  is linearly independent
- $Ax = b$  has a unique solution for all  $b \in \mathbb{R}^n$  given by  $x = A^{-1}b$ .
- $T$  is onto
- $T$  is one-to-one
- $T$  is invertible
- $A$  is invertible

## Subspaces

Here's the definition of subspaces. Here's an example of what is a subspace. Here's an example of what isn't a subspace.

The solutions to homogeneous equations are subspaces. This is why we care.

Introduce kernel and range.
